

ICS 2021 Problem Sheet #9

Problem 9.1: JK flip-flops

(1+1+1+1 = 4 points)

JK flip-flops, also colloquially known as jump/kill flip-flops, augment the behaviour of SR flip-flops. The letters J and K were presumably picked by Eldred Nelson in a patent application.

The sequential digital circuit shown below shows the design of a JK flip-flop based on two SR NAND latches. Assume the circuit's output is $Q = 0$ and that the inputs are $J = 0$ and $K = 0$, and that the clock input is $C = 0$. (You can make use of the fact that we already know how an SR NAND latch behaves.)

- Suppose J transitions to 1 and C transitions to 1 soon after. Create a copy of the drawing and indicate for each line whether it carries a 0 or a 1.
- Some time later, C transitions back to 0 and soon after J transitions to 0 as well. Create another copy of the drawing and indicate for each line whether it carries a 0 or a 1.
- Some time later, J and K both transition to 1 and C transitions to 1 soon after. Create another copy of the drawing and indicate for each line whether it carries a 0 or a 1.
- Finally, C transitions back to 0 and soon after J and K both transition to 0 as well. Create another copy of the drawing and indicate for each line whether it carries a 0 or a 1.

Problem 9.2: ripple counter using d flip-flops

(2+1 = 3 points)

The following circuit shows a 3-bit ripple counter consisting of three positive edge triggered D flip-flops and a negation gate on the clock input C .

- Complete the following timing diagram. Assume that gate delays are very short compared to the speed of the clock signal (i.e., you can ignore the impact of gate delays).

- b) Can you make ripple counters arbitrary “long” or is there a limit on the number of D flip flops that can be chained? Explain.

Problem 9.3: *integer expression simplification (haskell)*

(2+1 = 3 points)

Our goal is to simplify integer expressions that may include constants and variables and which are constructed using a sum and a product operator. For example, we want to write a program that can simplify $(2 \cdot y) \cdot (3 + (2 \cdot 2))$ to $14 \cdot y$. We can represent expressions in Haskell using the following data type:

```
1 data Exp = C Int           -- a constant integer
2           | V String       -- a variable with a name
3           | S Exp Exp      -- a sum of two expressions
4           | P Exp Exp      -- a product of two expressions
5           deriving (Show, Eq)
```

We use the following rules to simplify expressions:

- S1 Adding two constants a and b yields a constant, which has the value $a + b$, e.g., $3 + 5 = 8$.
- S2 Adding 0 to a variable yields the variable, i.e., $0 + x = x$ and $x + 0 = x$.
- S3 Adding a constant a to a sum consisting of a constant b and a variable yields the sum of the $a + b$ and the variable, e.g., $3 + (5 + y) = 8 + y$.
- P1 Multiplying two constants a and b yields a constant, which has the value $a \cdot b$, e.g., $3 \cdot 5 = 15$.
- P2 Multiplying a variable with 1 yields the variable, i.e., $1 \cdot y = y$ and $y \cdot 1 = y$.
- P3 Multiplying a variable with 0 yields the constant 0, i.e., $0 \cdot y = 0$ and $y \cdot 0 = 0$.
- P4 Multiplying a constant a with a product consisting of a constant b and a variable yields the product of $a \cdot b$ and the variable, e.g., $3 \cdot (2 \cdot y) = 6 \cdot y$.

The usual associativity rules apply. Note that we have left out distributivity rules.

- a) Implement a function `simplify :: Expr -> Expr`, which simplifies expressions that do not contain variables. In other words, `simplify` returns the (constant) value of an expression that does not contain any variables.
- b) Extend the function `simplify` to handle variables as described above.

Submit your Haskell code plus an explanation (in Haskell comments) as a plain text file. Below is a template providing a collection of test cases.

```

1  module Main (main) where
2
3  import Test.HUnit
4
5  data Exp = C Int          -- a constant integer
